

Coherence relations and DRD identification: theory and analysis

Ted Sanders (Utrecht University)

Wilbert Spooren (Radboud University Nijmegen)

Crash course statistical testing of reliability: Cohen's kappa

Practice in using corpora

- In discourse analytical research we often make use of corpora, to test our hypotheses
- For this we need to analyze corpora
- Frequently a researcher works in isolation
- Often in two or more experts annotate phenomena in a corpus and discuss over unresolved annotation issues
- Question: how solid are these data?

Practice in using corpora

- In empirical research we expect our data (=annotations) to be robust
- One of the criteria for robustness is reproducibility
 - if another researcher replicates the research, (s)he should be able to produce more or less the same data
 - if the same researcher replicates his/her research at a later time, it should produce more or less the same data
- This robustness should be tested

Measures for intercoder agreement

- Statements of the type “the corpus was annotated and coding problems were discussed”
- Percentages observed agreement between two or more coders
 - problem: no indication of chance agreement

Ann1\Ann2	Cat 1	Cat 2
Cat 1	30	5
Cat 2	6	40

$$\text{Perc. obs. agr.} = (70/81) * 100 = 86.4 \%$$

$$\text{Perc. ch. agr.} = ((36/81) * (35/81)) + (45/81) * (46/81) * 100 = 50.7 \%$$

Measures for intercoder agreement

- Chance-corrected measures
 - Measures for two coders (unweighted)
 - Measures for more than two coders (unweighted)
 - Measures for two or more coders (weighted)
- Unweighted: all disagreements weigh equally heavy
Weighted: some disagreements weigh heavier than others

Two coders, unweighted

- All formulas for coefficient are the same
$$\frac{(\text{observed agreement} - \text{expected agreement})}{(1 - \text{expected agreement})}$$
- Terminology
 - S
 - (Cohen's) κ
 - (Scott's) π
- they differ in the way expected agreement is calculated
 - (least sophisticated: S; most sophisticated: π)
- Here only κ

Two coders, unweighted

- Example

	Cat 1	Cat 2
Cat 1	30	5
Cat 2	6	40

$$A_o = (30+40)/81 = .86$$

$$A_e = ((36/81) * (35/81)) + (45/81) * (46/81) = .51$$

$$\kappa = (A_o - A_e) / (1 - A_e) = (.86 - .51) / (1 - .51) = .71$$

Interpretation:

Figure 1

Kappa values and strength of agreement according to Landis and Koch (1977).

Two coders, unweighted, in SPSS

The screenshot shows the SPSS Data Editor window with a dataset named 'Untitled1 [DataSet0]'. The dataset has five variables: 'Rater_1', 'Rater_2', 'Freq', and two unnamed variables labeled 'var'. The data is as follows:

	Rater_1	Rater_2	Freq	var	var
1	1	1	30		
2	1	2	5		
3	2	1	6		
4	2	2	40		
5					
6

11					
12					
13					
14					
15					
16					
17					
18					
19					
20					

The 'Weight Cases' dialog box is open, showing the following options:

- ☐ Do not weight cases
- ☒ Weight cases by

The 'Frequency Variable' is set to 'Freq'. The 'Current Status' is 'Do not weight cases'. The 'OK' button is highlighted.

At the bottom right of the SPSS window, the 'Weight On' button is circled in red.

Two coders, unweighted, in SPSS

Rater_1 * Rater_2 Crosstabulation

Count

		Rater_2		Total
		1	2	
Rater_1	1	30	5	35
	2	6	40	46
Total		36	45	81

Symmetric Measures

		Value	Asymp. Std. Error ^a	Approx. T ^b	Approx. Sig.
Measure of Agreement	Kappa	,724	,077	6,520	,000
N of Valid Cases		81
